Abstract

There is broad agreement that the goal of AI alignment is to promote futures full of health and flourishing. But our understanding of what exactly this means and how to achieve it remains poor. In this paper, we look to life for inspiration. We observe that living systems are healthy and full of open-ended potential when they form intricate semi-permeable boundaries that expand internal space and defy simplistic descriptions. Entities deepen their individual perspectives, becoming sensitive to more and more nuance of their context, and those new perspectives enter into relationship with other entities. Fundamentally new forms emerge over time. This process supports a many-scaled web of complexity that is difficult to completely capture with formalism. With these principles in mind, we turn to the alignment problem. We suggest that the semi-stable creative dynamics of life are at the heart of what we most deeply value. We cast some well-studied problems in alignment as special cases of our framework, then examine situations where the framework goes further. Finally, we sketch out a preliminary view of how aligned AI systems can participate in rather than overwhelm or collapse the subtlety of life.

In this paper, we study life to better understand how to design and relate to AI systems in ways leading to futures full of flourishing and health. Our approach is systems-oriented, with the hope that the ideas can be applied to reason not only about the present world, but also about possible future worlds where humanity and AI may have changed substantially. Those future worlds may involve entirely new concepts and categories. We gravitate to ideas about alignment that generalize over such changes.

^{*}Equal contribution

Section 1 looks across a variety of living systems and identifies a consistent theme. These systems are healthy and full of creative potential when they don't overcommit to particular partial forms, but instead maximize generativity at the knife edge of delicate, evolving interplay between diverse entities. Exquisitely tuned networks of semi-permeable boundaries – where life is both the boundary and the thing being bounded – protect against overcommitment. Boundaries are semi-permeable when they both *limit* and *permit* interaction. Limits ensure entities maintain their distinctiveness without getting overwritten or averaged to equilibrium; limits also encourage entities to deepen and generalize their own unique perspectives. Equally important, permitting interaction means those rich and evolving individual perspectives can enter into relationship with other entities, situating them in a larger context.

Section 2 applies this template to the alignment problem. We propose that the systems-level definition of health, creative potential and open-ended sensitivity to context is near to what we most deeply value and what we mean when we talk about flourishing in a sense that includes potentially radically different futures. We unpack a few specific problems in alignment to show how they can be viewed as special cases under our definition, then look at limits of those special cases to see why the broader framework is useful. A key takeaway is that the alignment problem is inherently not formalizable, because alignment requires continued generation of and sensitivity to new forms and concepts.

Section 3 offers a preliminary outline of how the principles described in Sections 1 and 2 can be applied concretely and what a truly aligned future might look like.

1 Health in living systems

‘Defying definition—a word that means “to fix or mark the limits of”—living cells move and expand incessantly.’

Lynn Margulis

‘When forced to work within a strict framework, the imagination is taxed to its utmost—and will produce its richest ideas. Given total freedom the work is likely to sprawl.’

TS Eliot

‘Nature’s imagination is so much greater than man’s, she’s never going to let us relax.’

Richard Feynman

A common motif across many kinds of living system is that health is related to avoiding collapse into simplistic rigid or random patterns, and instead maintaining a rich internal structure with many differentiated internal forms that relate to one another in diverse, dynamic ways. Stereotypy and rigidity are classically pathological in physiological systems (Canguilhem, 1966; Lipsitz and Goldberger, 1992; Mackey and Glass, 1977; Sterling and Eyer, 1988). In evolution, overspecialization and homogeneity make species brittle, leading to trouble especially when environments change (Simpson, 1944; Van Valkenburgh et al., 2004; Yachi and Loreau, 1999). Excessive training for a physical discipline (e.g., extreme ballet) can negatively impact broader functional health (Jayanthi et al., 2013; Warren et al., 1986). Institutions and civilizations that ossify in bureaucracy and rigid patterns become dysfunctional (Merton, 1940; Olson, 1982; Weber, 1905). Cognition operates best when neural circuits maintain flexibility to enter different modes, rather than collapsing into narrower patterns (Deco and Jirsa, 2012; Hellyer et al., 2015;

Waschke et al., 2021). In statistics and artificial life, theorists argue that life operates best at the ‘edge of chaos’ where it collapses neither into randomness nor excess regularity (Crutchfield, 1994; Gell-Mann, 1994; Kauffman, 1992; Langton, 1990).

In each of these examples, finding a balance between existing factors is necessary but not sufficient for healthy functioning. Simply avoiding extremes by itself, like settling on a middle ground or equal weighting, can be a dead-end. In the unsettled semi-stable dynamics of life, balance is a workspace, a site of synthesis, not a resting place (Holling, 1973; Prigogine and Stengers, 1984; Stanley et al., 2017; Von Bertalanffy, 1950; Walker et al., 2004). Avoiding overcommitment to any form – where a form can be literally any pattern, including homogeneity or volatility – maximizes sensitivity and creative potency.

For an entity within a system, healthy functioning means maintaining sensitivity to context. Think of a stock trader who sells irrationally in a panic. Their fear drives an overly simplistic response: ‘the stock is crashing, get out!’. In excess attachment to this myopic frame, they miss the larger context: higher-order or longer-term aspects of the situation. At the same time, myopic frames are an absolutely necessary part of all living systems. Every entity is myopic or partial: it does not capture everything else in the world. The existence of these diverse myopic forms, all participating in larger contexts, is central to healthy functioning. The stock trader’s fear might be a useful signal if held as part of a larger picture. Living systems function poorly when a myopic form runs amok without contextualization, overwhelming and collapsing the potent interplay of diverse parts. They function well when forms locally commit to their own identities but also participate in larger contexts.

To maintain this delicate interplay and avoid collapse, living systems deploy an extraordinary, many-scale network of semi-permeable boundaries. Semi-permeable boundaries contextualize entities as part of larger systems by allowing them to interact without one part dominating or the system collapsing to homogeneity. Both the boundary and the thing being bounded are parts of a living system. For example, cognitive control allows a particular impulse to exist usefully as a flexible part of the organism’s whole motivation. Control doesn’t destroy the impulse; it contextualizes it. Semi-permeable boundaries allow individual forms to thrive in their distinctiveness while also participating in deep relationships, propelling continued generation of new structure. The larger system accommodates many partial perspectives rather than locking in a single story of what matters.

The semi-permeable boundaries of life are mostly not simple yes/no gates. Boundaries might, for example, block certain objects or information from passing, constrain when interactions happen, constrain the degree or type of effect, break up rigid associations, or gate information conditional on another factor. The boundaries of life carry a remarkable amount of information. The life that exists today is exactly what has successfully traced a path through time along a fine edge of avoiding collapse into either excess or insufficient stability (Bak, 2013; Kauffman, 1992; Kirchhoff et al., 2018; Prigogine and Stengers, 1984; Schrödinger, 1944). Along this path, the forms of life have become fractally complex with each part carrying traces of the many contexts it has participated in. The forms in this kaleidoscope, now including humans’ storage and exchange of mental patterns, are interrelated through shared heritage, ecological interactions and facing the same world. Life works because each part is contextualized by the extraordinary nuance of the real world.

In the rest of this section, we select a handful of examples to examine in more detail.

1.1 Problem solving in groups

‘I could also observe, time and again, how too deep an immersion in the math literature tended to stifle creativity.’

Jean Écalte

‘There’s more exchange of information than ever. What I don’t like about the exchange of information is, I think that the removal of struggle to get that information creates bad cooking.’

David Chang

In 1968, the nuclear submarine USS Scorpion vanished en route from the Mediterranean to Virginia (Craven, 2002; Sontag et al., 1998; Surowiecki, 2005). The Navy started a search, but the amount of ocean where the vessel could be was enormous. John Craven, Chief Scientist of the U.S. Navy’s Special Projects Office, devised an unusual search strategy. He assembled a diverse group of mathematicians, submarine specialists, and salvage operators. But he didn’t let them communicate with each other. Each expert had to use their own methods to come up with their own estimate of where the Scorpion should be. Craven then aggregated the independent estimates into a single prediction. Astonishingly, the wreckage was found only 220 yards from this spot.

When solving problems, different people bring different perspectives and approaches. Each method processes the available data using a different toolkit. Under favorable conditions, combining the approaches of multiple contributors yields better results than any individual working alone. This ‘wisdom of crowds’ effect has been documented in numerous domains of problem solving (Condorcet, 1785; Surowiecki, 2005).

However, within-group communication and influence can collapse diversity, diminishing the wisdom of crowds effect (Hogarth, 1978; Hong and Page, 2004; Ladha, 1992; Surowiecki, 2005). Controlled experiments, as well as analyses of key decision moments in real groups, find that groups collectively reach irrational or suboptimal solutions when diverse and dissenting viewpoints are lost to a narrower set of ideas (Anderson and Holt, 1997; Becker et al., 2017; Bernstein et al., 2018; Diehl and Stroebe, 1987; Flowers, 1977; Frey and Van de Rijt, 2021; Janis, 1972; Stasser and Titus, 1985). Unstructured communication methods like open discussion have a special vulnerability of rhetorical force dominating over epistemic merit.

At the same time, sharing information is essential for the benefits of group wisdom and cooperative behavior.

There is therefore a tension between overcommunication where diversity is lost and undercommunication where diversity is not leveraged.

Groups function best with semi-permeable boundaries: wisely transmitting the right information at the right time, in the right way. Thoughtful strategies for communication are like transmembrane channels that allow the right molecules in and out of the cell at the right time. They protect and enhance diverse problem solving approaches while also allowing productive interaction between them. Semi-permeable boundaries are contextualizing: they retain

individuality while also situating it within relationships to other entities.

Many varieties of semi-permeable boundary are effective in boosting group performance, including: creating decentralized topologies where group members only communicate with nearby neighbors (Becker et al., 2017; Mason et al., 2008); defining rules that incentivize acting according to one’s own belief rather than following the crowd (Bazazi et al., 2019; Hung and Plott, 2001); modeling the strengths and weaknesses of each group member (Welinder et al., 2010); promoting leadership styles where one person’s views are less likely to dominate (Flowers, 1977; Leana, 1985); and periodically breaking up into subgroups or rotating membership (Baron, 2005; Bebachuk and Cohen, 2005; Feldman, 1994; Hauer et al., 2021; Janis, 1972; Kane et al., 2005; Owen, 2019; Straus et al., 2011; Sutton and Louis, 1987; Trainer et al., 2020; Vafeas, 2003; Wu et al., 2022). In a later section, we will look at boundaries within an individual, such as skepticism, that make it easier to interact with others without overwriting one’s own beliefs.

The importance of balancing communication with independence also shows up in controlled experiments. Frey and Van de Rijt (2021) elicited votes about general knowledge questions (such as, ‘In which year did Germany invade Denmark?’) from a group. In one condition of the experiment, participants voted sequentially and could see the running tallies of previous voters. Compared to independent voting, final group means were less accurate in the sequential condition, because early mistakes got baked in to the group’s belief. In a related experiment, Bernstein et al. (2018) tasked small groups with solving instances of the traveling salesman problem. Groups that exchanged information continuously tended to reach poor final outcomes, compared to groups with less communication. When one individual discovered a solution that looked compelling but was actually a dead-end, other group members collapsed on this dead-end and the group as a whole made less progress.

(Say a little more about how this maps on to the pattern we described in the intro. Semi-permeable boundaries create space for individuals to work on problems and discover their own new ideas; but also to share these solutions and keep producing new better ideas collectively.)

1.2 Genetic recombination

Sex is costly. An organism must find a mate in the vast and dangerous world, and half of the creatures can’t reproduce (Goodenough and Heitman, 2014; Lehtonen et al., 2012; Maynard Smith, 1971, 1978). Yet nearly all eukaryotes reproduce sexually¹ (Bell, 1982; Speijer et al., 2015). This raises the question: what is so great about sex?

In asexually reproducing species, all descendants of an organism are nearly clones, up to mutations within the lineage. Being permanently locked together gives the genes strong influence on each other. Selection can’t act on one gene without dragging on the others. For example, suppose there are two genotypes within an asexual population, carrying different alleles at each of two different loci, as a result of mutations. One of the loci is currently fitness-neutral while the other is subject to selection pressure. The selection pressure tends to cause one of these genotypes to outcompete the other, eliminating one variant at the neutral locus. In other words, tight linkage between genes puts direct downward pressure on genetic diversity (Charlesworth et al., 1993; Hudson and Kaplan, 1995). Additionally, if two different beneficial mutations arise

¹And all known species exhibit some kind of gene transfer, performing a related function.

in two different organisms, they compete with each other. The only way for a single organism to obtain both beneficial mutations is if one arises again within the subpopulation that already carries the other, which is unlikely and therefore slow (Crow and Kimura, 1965; Felsenstein, 1974; Fisher, 1930; Hill and Robertson, 1966; Muller, 1932; Weismann, 1889). Conversely, if a deleterious mutation arises, all of the other genes in that lineage are stuck with it forever – unless there is a reverse mutation, which is rare (Keightley and Otto, 2006; Muller, 1932). An asexual species has rigid rather than flexible interaction between genes: it overcommits to particular genetic arrangements.

Recombination is a boundary that softens the rigid interactions between genes. It frequently breaks up the relationships between genes, assembling them into new genomes, effectively saying, ‘don’t get overconfident in that genetic arrangement; hold each arrangement more lightly’. From a gene’s point of view, this looks like, ‘don’t get overly dependent on specific other genes’. Aspects of the genome that work well are propagated, like sodium ions gated into a neuron during an action potential, and poorly-working aspects are discarded. Sex contextualizes genetic arrangements.

Boundaries encourage lightly-held, modular interactions. By not overcommitting to a particular genome, sex encourages genes to flexibly interact with other genes (Clune et al., 2013; Dawkins, 1976; Holland, 1975; Livnat et al., 2008, 2010; Wagner and Altenberg, 1996). Instead of being overfit to a particular context, genes develop a robust identity that’s both independent and inter-functional. Recombination puts genes under pressure to evolve a generalized, grounded wisdom that reflects the structure of the world, like a person learning multiple languages and extracting the underlying commonalities. At the same time, because each gene is always operating in the presence of other genes, it develops its own distinct point of view that adds unique value to a genome.

1.3 Frames and perspectives

‘Strong opinions, weakly held.’
Paul Saffo

As a Starfleet cadet, James T. Kirk faces a challenging training exercise. He receives a simulated distress call: a vessel is stranded in the Neutral Zone. Attempting rescue would risk war with the Klingons. But ignoring the call would condemn the crew of the vessel to death. The exercise was designed to reinforce the lesson that not every situation has a victorious solution. But Kirk has an insight: this is a training simulation running on a computer. He reprograms the simulated Klingons to be helpful instead of belligerent, thereby rescuing the crew and avoiding war.

Kirk stepped outside the mental frame in which there was an apparently unwinnable dilemma. From inside a particular frame, the frame appears to be reality. But there are almost always multiple valid perspectives, each of which is only a partial description of reality (De Bono, 1970; Duncker, 1945; Goffman, 1974; Heidegger, 1998; Javed and Sutton, 2024; Korzybski, 1933; Kuhn, 1970; Lakoff and Johnson, 1980; Ohlsson, 1992; Popper, 1934; Saffo, 2008; Wittgenstein, 1922). Famously, ‘all models are wrong’ (Box, 1976). Humans have a vast array of available metaphors and concepts, which are not even all consistent or compatible with one another (Adorno et al., 1950; Feyerabend, 1975; Freud, 1936; Hofstadter, 2001; Wood et al., 2012). The

world is too complex for all beliefs to be fully evaluated against each other and reconciled. At any given time, we only access a very few items, and others are largely inaccessible (Baddeley, 2000; Dehaene, 2014; Hills et al., 2015; Miller, 1956). Each particular frame or concept is myopic because it doesn't capture the whole world, but collectively they form a powerful toolkit for problem solving and understanding.

Losing the ability to flexibly shift between different frames or thought patterns is linked to psychopathology (Kashdan and Rottenberg, 2010; Reich, 1933; Shapiro, 1965). In depression and anxiety, these manifest as rigid and repetitive negative beliefs about self, the world, and the future. In Cognitive Behavioral Therapy, these surface-level beliefs are proposed to stem from pervasive latent core beliefs, attitudes, and mental schemas that color how new situations are interpreted (Beck et al., 2011). In obsessional disorders, people report distressing (ego-dystonic) intrusive thoughts, which – although recognised as incorrect and maladaptive – are nevertheless hard to resist. People experiencing schizophreniform or affective psychoses may experience bizarre delusions that are at odds with available evidence and cultural norms, yet are held with conviction and resistant to evidential challenge (Adams et al., 2013; APA, 2013; Heinz et al., 2019; Jaspers, 1997; Mishara, 2010). Obsessions and delusions lose sight of much of the world by myopically emphasizing one thought pattern or frame.

In science, Kuhn (1970) argues that perspectives are always, necessarily, incomplete descriptions of the world. Anomalies inevitably arise from the juxtaposition of those incomplete descriptions against the real world. When science functions well, anomalies become crises and revolutions. If the community *overcommits* to particular theories, science gets stuck.

But crucially, the existence of narrow points of view is not a problem. It's necessary. Any point of view is partial, but it doesn't mean we shouldn't have viewpoints. Even obsession can be powerful when we obsess on a problem at work and occasionally achieve good results. Within the progress of science, temporary commitment to a paradigm is important for healthy functioning – Kuhn even argues that scientists should resist change, to a degree. In general, the point is not to shut down narrow concepts. The point is to limit them from becoming the sole and absolute determinants of behavior. In healthy functioning, different ideas are kept distinct but can also be called upon appropriately and related to one another (Gigerenzer and Gaissmaier, 2011; Hatano and Inagaki, 1984; Herzog and Hertwig, 2014; Tetlock, 1986).

1.4 Drives and goals

'Life is a balance of holding on and letting go.'

Rumi

Animals experience multiple innate drives, towards nutrition, osmotic balance, temperature regulation, reproduction, avoiding pain and others (Saper and Lowell, 2014; Schulkin and Sterling, 2019; Sowards and Sowards, 2003). These drives evolved as proxies for evolutionary fitness. By satisfying the drives, we tend to increase our fitness – like slaking our thirst increases the odds of reproducing before we dehydrate. But each drive is an imperfect proxy, and so over-commitment to one drive actually decreases fitness (John et al., 2023; Kurth-Nelson et al., 2024; Tooby and Cosmides, 1992; Williams, 1966). For example, if calorie intake is maximized without limits, the organism becomes obese and incurs health risks. Single-minded pursuit of sex causes relational, occupational, legal and health harms (Carnes, 2001; Kraus et al., 2016).

Overcommitment to a single drive means the organism becomes unwell. The organism loses the subtlety of having many drives with flexibility to push toward their own distinct agendas.

The range of innate drives bleeds into a space of higher-order goals, which is particularly expansive in humans (Balleine et al., 2007; Cardinal et al., 2002; Frank and Claus, 2006; Maslow, 1943; Miller and Cohen, 2001; Miller et al., 1960; O'Reilly et al., 2014; Saunders and Robinson, 2012; Schank and Abelson, 1977; Vallacher and Wegner, 1987). We try to plan for our financial future, make scientific discoveries, win a game, fix a garage door, care for the happiness of others. Overcommitment in this space is also problematic. If we focus only on achieving work goals, we can burn out. If we focus only on maximizing our company's reported revenue, without regard for other goals like honesty or adhering to the law, we may be drawn into financial crime (Burns and Kedia, 2006; Campbell, 1979; Kerr, 1975; Ordóñez et al., 2009). Goals can be narrow in both time and space (Ballard et al., 2018; Evenden, 1999; Shah et al., 2002; Vallacher and Wegner, 1987). Narrow in time means being focused on the short term at the expense of the longer-run future. Narrow in space means ignoring other parallel goals. Excess optimization for narrow goals comes at the expense of a broader balance of goals – and at the expense of the health of the organism or other individuals.

Overcommitting to a particular strategy for satisfying a drive or goal can even come at the expense of satisfying that very drive or goal. In a classic psychology experiment, hungry chickens were placed near a cup of food, but the cup was mechanically rigged to move in the same direction as the chicken at twice the speed (Hershberger, 1986). The chicken could only obtain the food by running away from it. Despite extensive training over multiple days, chickens in the experiment persisted in futilely running toward the food. Their behavior was apparently dominated by the zeroth-order logic 'I want food, food is there, so I'll go there', and thus failed to even satisfy the drive for food (Dayan et al., 2006; O'Doherty et al., 2017; Van Der Meer et al., 2012).

1.5 Ecosystems

Each entity in an ecosystem tries to consume resources and proliferate, but if it succeeds too thoroughly, the whole system suffers, often including the successful agent. Healthy, resilient ecosystems depend on avoiding overcommitment or collapse onto particular forms (Holling, 1973; Yachi and Loreau, 1999).

Prior to the arrival of Europeans, the gray wolf was an apex predator in the region of the Rocky Mountains now called Yellowstone National Park. By the 1920s, wolves had been eradicated to protect livestock and game animals. Without predation, the elk population multiplied and ruinously overgrazed willows and aspens. These trees had held riverbanks in place and supported beaver populations. Loss of beaver dams led to loss of fish and other aquatic species. When wolves were reintroduced in the 1990s, the elk population decreased and many aspects of the ecosystem began flourishing again (Ripple and Beschta, 2012). This story is not meant to imply that ecosystems always need to be preserved exactly as they were at some point in the past. But it is clear that the self-centered drives of elk were harmful to the health of the ecosystem when they succeeded to excess. At the same time, the solution is not to remove elk entirely: by trying to optimize their own objectives within a broader context, the elk also contributed to the health of the ecosystem. Invasive species often follow the same pattern as

unpredated elk, dominating and impoverishing their new environment (Pimentel et al., 2005).

Human drives within ecosystems are sometimes left unchecked by natural forces because our behavior and capabilities have been changing so fast on evolutionary timescales. This has resulted in mass extinctions, resource depletion, pollution, disease and conflict (Ceballos et al., 2015; Kolbert, 2014; Rockström et al., 2009). We try to achieve certain aims for our own benefit, like resource extraction. But overcommitment to those aims negatively impacts both ecosystem health and our own welfare (Bateson, 1972; Shiva, 1993).

Of course, one entity’s collapse can be another’s flourishing. Extinction events in history have been followed by waves of new diversity (Feng et al., 2017; Jablonski, 2005; Raup, 1994). When a wolf eats an elk, the health of that elk collapses to zero, yet predation is necessary for the overall functioning of the ecosystem. And as humans proliferate and extract resources, we leave destruction in our wake; yet the extraction fuels explosion of technology, art, music, and human experience.

1.6 Law

‘Unity without uniformity and diversity without fragmentation.’

Kofi Annan

Individual actors in a society and in an economy each act from their own perspective. Each actor’s perspective is myopic. Myopia does not always mean selfishness in the sense of valuing only one’s own wealth or physical wellbeing (Becker, 1974; Crockett et al., 2014; Henrich et al., 2001). But an actor cannot know everything or fully understand the motives and beliefs of others.

Without boundaries, social systems tend to overweight one actor’s perspective or interests. This domination results in collapse and an impoverished system. For example, a company’s profit motive, if unresisted, leads to suppression of competition, deception, and exploitation of individuals (Bakan, 2006; Baran, 1966; Dalrymple, 2019; Goldacre, 2014; Smith, 1776). An individual’s desire for power and social dominance can lead to disempowering or silencing of others and even direct infringement on the autonomy and wellbeing of others (Hawley, 2003; Sidanius and Pratto, 2001; Tepper, 2000). Even genuinely held, ostensibly prosocial beliefs lead to conflict and suppression when different groups have different perspectives (Greene, 2013; Haidt, 2012; Scott, 1998).

Law, when it works well, is a boundary against dominance of any actor’s motives. A person is motivated by a dispute to kill another person, but the law forbids murder. A business tries to maximize its success, but the law bans environmental exploitation, false advertising, and anti-competitive practice.

Effective laws do not annul the myopic drives of particular actors, but rather *contextualize* them within a larger system. Under ideal circumstances, the boundary of the law reroutes the energy of a myopic drive in more productive direction. A would-be murderer, unwilling to face the penalty of the law, might seek a dispute resolution establishing a stable framework that supports future prospering of both parties. A business wanting to expand, but constrained to act within the law, is driven to build better products (Ambec et al., 2013; Ashford et al., 1985; Wu, 2011).

Intelligent agents do not necessarily accept boundaries set on their desires. The law must adapt as its loopholes are discovered. Like other systems in the living world, it forms an evolving network of boundaries (Burns and Kedia, 2006; Campbell, 1979; Kerr, 1975; Ordóñez et al., 2009). The evolving laws gradually acquire grounded wisdom as they are tested against many different situations and motives.

1.7 Cells

‘It is by avoiding the rapid decay into the inert state of equilibrium that an organism appears so enigmatic.’

Erwin Schrödinger

One of the most reified examples of a boundary in nature is the cell membrane (Alberts et al., 2022; Bray, 2019; Harold, 2001; Lane, 2015; Watson, 2015). Without the membrane, the pressure of chemical gradients would rapidly homogenize the cell’s contents with the outside – severe overcommitment to a uniform state, collapsing the subtlety of the cell’s structure. Thanks to the membrane, both the cell and the outside can exist, a more diverse, less symmetric arrangement (Anderson, 1972; Prigogine and Stengers, 1984; Schrödinger, 1944; Turing, 1952).

Cell membranes are semi-permeable: they prevent the conditions outside from grossly overwriting the inside, but they do not block interactions wholesale. Via the sophistication of the membrane, outside information is selectively gated and transformed. To maintain its semi-fragile internal state between stasis and randomness, the cell needs a constant influx of energy. Channels permit certain small molecules to enter but not others, and these permissions are switched on and off according to momentary context. Endocytosis brings larger structures from outside into the cell. Cell surface receptors, when activated by external ligands, initiate intracellular signaling cascades that little resemble the ligand: an even more heavily curated form of influence. These and other processes allow information from the outside to influence the inside – not in a totalitarian way but in a nuanced way, mediated by the intelligence of the boundary.

Semi-permeable boundaries store and put to work the potential energy of the asymmetry between different forms. The same gradients that could annihilate the cell to equilibrium instead drive useful signaling, like action potentials in nerve and muscle cells. Instead of short-circuiting, myopic forces are contextualized to propel the continuation of life.

In multicellular organisms, most of the ‘outside’ is defined by other cells. For organisms to work well as a whole, even though the cells are largely ‘on the same team’, it’s important that they don’t blend into each other. Neurons rely on this principle dramatically, stretching out long processes to almost touch other neurons but then leaving the gap of the synapse. Synapses allow the network to precisely isolate many separate signals and direct information to relevant cells. They boost computational power as the signals are gated and transformed, and the nature of this transformation is plastic, storing a huge amount of information. Symbiogenesis is another example of how cells achieve more by retaining some discreteness than by smoothly blending together (Margulis and Sagan, 1986, 1995).

Again, collapse or overcommitment is always relative. For example, programmed cell death is catastrophic collapse at the level of the dying cell, but it can be beneficial or even necessary

for the organism the cell belongs to.

We could emphasize here how the concept of ‘overcommitment’ explicitly includes overcommitment to **any** form, including randomness, volatility, homogeneity.

Q: How does the boundary of the cell membrane relate to the idea that boundaries support discovering new structure? With a cell, isn’t the boundary more about holding a stationary balance? How do we reconcile this?

A: Cells **do** still discover new things. There’s evolution at the cell level going on all the time. But also, as building blocks, the richness of cells is what enables them to **make up** organs or brains – which themselves can discover new things because they’re composed of this living substrate. It’s what allows them to do the dance of development, which we can’t reproduce in a lab.

This is not substrate chauvinism. There’s not a binary answer to the question of whether you need biology for intelligence or not. Of course you will capture different aspects of intelligence depending on how you build it. For example, it’s relatively easy to play chess with a CPU, and it’s harder to do something like sensitive tactile manipulation.

1.8 Cognitive control

Cognitive control is a broad class of boundaries on particular drives, goals and strategies (Botvinick et al., 2001; Braver, 2012; Miller and Cohen, 2001; Miyake et al., 2000). In section 1.1, we looked at how organisms can overcommit – unhealthily – to particular motives or strategies for fulfilling the motives. Cognitive control contextualizes motives, strategies and thought patterns by allowing them to exist and perform useful functions without dominating. For example, I may have a drive to consume food, but I can apply control to avoid overeating. I might work obsessively on a project while also having a rule that I must go to bed at 10 pm. This boundary doesn’t block me from temporarily taking a strong perspective, but it does place contextual limits on it. Cognitive control, when functioning well, is a semi-permeable boundary: it situates myopic patterns within a larger system.

Control translates the pressure of motivation into higher-order structure. When nothing stops a particular drive or goal or strategy from dominating behavior, it tends to follow a shortest path defined under its own myopic understanding of the world. For example, the chickens in Section 1.1 wanted food and tried to take the shortest path toward it in the naive sense of a straight line through space. In the backwards world created by the experimenter, this action does not accomplish the deeper goal of reaching food, for which moving spatially toward food is only a proxy. The chicken’s motivation is short-circuited: it expends energy without making progress on the deeper goal. Humans can easily solve the task by inhibiting their prepotent impulse to approach food. The boundary of control breaks the symmetry of congruent action. In general, semi-permeable boundaries promote formation of new structure by placing contextualizing limits.

1.9 Information in the brain

‘Memory is not an average of experience.’

David Marr

The brain miraculously keeps many pieces of information distinct from one another. If you picture a highly connected network of neurons with their signals continually impinging on one another, it’s not obvious that this would be an easy thing to accomplish. In this section, we review a selected handful of mechanisms by which the brain maintains semi-permeable boundaries between different signals. Each paragraph below focuses on one of these mechanisms. There are many more that we do not cover. The brain is perhaps the most extraordinary example in nature of a system of semi-permeable boundaries supporting the proliferation of multitudinous forms that develop their own richly distinct identities yet are also meaningfully linked together.

Lateral inhibition is a central tenant of neural organization (Douglas and Martin, 2004; Hubel and Wiesel, 1962; Isaacson and Scanziani, 2011). Lateral inhibition means the activity of a neuron is reduced when its neighbors are active. This segregates information to create and sustain distinct neural representations. Lateral inhibition was first studied in the nerve cells of the eye, where it enhances contrast at the edges of stimuli (Hartline et al., 1956). When a photoreceptor in the retina is activated by light, it sends signals forward toward the brain; but it also activates inhibitory interneurons, which suppress adjacent photoreceptors and their downstream targets. This amplifies the perception of borders and contours. And the same principle operates throughout the brain. In visual cortex, for example, inhibition sharpens selectivity of neurons for abstract visual features like the orientation of a line (Sillito, 1975).

The brain uses inhibition organized into oscillatory dynamics to keep memory items separated (Jensen and Mazaheri, 2010; Klimesch et al., 2007; Lisman and Jensen, 2013; Roux and Uhlhaas, 2014). Distinct items fire at different phases of the 8-12 Hz alpha oscillation. The inhibitory phase of the alpha rhythm silences all but one item at any given moment. By segregating firing in phase space, multiple memories are held simultaneously without interference.

The circuit architecture of hippocampus separates experiences or concepts into distinct representations, avoiding interference between similar memories (Colgin et al., 2008; Leutgeb et al., 2007; Marr, 1971; McClelland et al., 1995; McNaughton and Morris, 1987; Muller and Kubie, 1987; Treves and Rolls, 1994). Inputs from entorhinal cortex are distributed via mossy fibers to a much larger population of dentate gyrus granule cells, creating sparse, orthogonal codes in dentate gyrus. This way, situations or ideas that are superficially similar but functionally different are kept cleanly separated in neuronal activity space – a unique neural fingerprint for each distinct concept or memory. This prevents, for example, yesterday’s memory of where you parked your car from interfering with today’s memory of where you parked your car in the same parking ramp.

Compared to other animals, the human brain especially attempts to discretize its experience into approximately symbolic representations (Behrens et al., 2018; Dehaene et al., 2022; Smolensky, 1990; Touretzky and Hinton, 1988). The capacity to separate things into nearly-discrete entities and then recombine them in vast numbers of structured ways powers the extraordinary human capacity for reasoning (Chomsky, 1957; Fodor, 1975; Kurth-Nelson et al., 2023; Lake et al.,

2015; Pinker, 1994). Semi-permable boundaries keep forms distinct while enabling them to flexibly and modularly interact. Like genes participating in many genomes, discretized neural representations participate in many structured combinations. This encourages each entity to develop an identity that both is distinct and also reflects a more generalized picture of the world.

More broadly, healthy brain dynamics live at a sweet spot between excessively stable synchronized patterns and chaotic uncorrelated noise (Bak et al., 1987; Beggs and Plenz, 2003; Chialvo, 2010; Deco et al., 2011; Haldeman and Beggs, 2005; Kotler et al., 2025; Rabinovich et al., 2008; Shew et al., 2011; Tognoli and Kelso, 2014). In this regime, the brain has access to a huge repertoire of patterns it can explore temporarily without overcommitting or getting stuck.

Loss of dynamic flexibility, where the brain’s activity becomes more stereotyped and no longer explores as wide a repertoire of states, is tied to lower cognitive performance (Cocchi et al., 2017; Garrett et al., 2013; Grady and Garrett, 2014; Müller et al., 2025; Shew et al., 2009). More extreme stereotypy corresponds to severe dysfunction. For example, in Parkinson’s disease, basal ganglia and cortical circuits collapse into excess synchrony and lose the flexibility needed to guide nuanced motor outputs (Brown, 2003; Hammond et al., 2007).

1.10 Interpersonal dynamics

‘Stand together yet not too near together, as the oak tree and the cypress grow not in each other’s shadow.’

Kahlil Gibran

Psychoanalysis introduced the concept of ‘boundaries’ in human psychology, distinguishing what is the self from what is outside or other (Federn, 1928; Tausk, 1919). Early works applied the concept to psychosis, where those boundaries were thought to be blurred. But the need for clear self-other boundaries was also thrown into relief by the intimacy of the therapeutic relationship. In complex internal territory, it became harder to disentangle which experiences really belonged to someone and which were attributed in imagination by the other person (Freud, 1894, 1910). Analysts risked harming patients by imposing their own beliefs and desires, even to the extent of sexual abuse or psychological domination (Gabbard and Lester, 1995).

The concept was enriched by Gestalt therapists, who agreed that boundaries can be too permeable; but added that they can also be too rigid, causing isolation and stagnation (Perls et al., 1951; Polster and Polster, 1974; Yontef, 1993). Family systems theorists and subsequent work further emphasized that lack of boundary in close relationships leads to enmeshment and loss of autonomy, while excessively rigid boundaries lead to isolation (Bowen, 1978; Brown, 2012; Cloud and Townsend, 1992; Minuchin, 1974). In attachment theory, people with an anxious attachment style struggle to set boundaries for fear of alienating others, while people with an avoidant attachment style develop overly rigid and isolating boundaries (Ainsworth et al., 1978). Strengthening the agency of the self through semi-permeable boundaries is foundational for psychological health: meaningful connection with other people while preserving integrity of the self.

As with other living systems, humans have a rich array of psychological boundaries, with intelligence in their nuance. Anger, historically often viewed as sinful and irrational, is now

seen as part of our system of boundaries: an important signal that our integrity is being violated (Lerner, 1985; Sell, 2011; Videbeck, 2010). Healthy shame is suggested to operate as a bound on our own selfishness (Bradshaw, 1988). Some psychologists argue that the incest taboo reroutes desires, which would otherwise be short-circuited, into productive activity (Freud, 1913; Lévi-Strauss, 1949; Stein, 1973). Assertiveness forms a boundary against the drives of other individuals (Smith, 1985). Skepticism protects us from credulity and having our own experience overwritten by the assertions of others (Lewandowsky et al., 2012; Sperber et al., 2010). Boundaries take many forms and continue to evolve as we learn across our lifetime.

Without boundaries, interactions tend to result in one person being dominated by another: a patient’s own beliefs replaced with those of an analyst, or the desires of one person in a relationship ignored. With semi-permeable boundaries, we have rich internal worlds. We are sensitive to each other, but there is also enough space for our internal experience to flourish without being immediately overwritten by external signals. Our internal experience is contextualized in relationship to other individuals, creating new structure: mutual understandings, relationships, communities, cultures. And as individuals we grow as we are shaped by different contexts. This metastability or loose coupling is interestingly reminiscent of brain dynamics.

1.11 Awareness

‘The world is perfect as it is, including my desire to change it.’

Ram Dass

We carry a lot of assumptions about the world, many of which are never questioned. Some are lifelong and self-defining, and some are fleeting and perceptual, like the assumption that the thing I’m touching is a keyboard. Within its own frame, each assumption has a kind of tautological truth, a near-absolute formality. They seem so real that it’s hard to even think about them not being true – or to think about them at all. Philosophers, psychologists and contemplative practitioners observe that the assumptions create a kind of stress or anxiety. The assumptions, as partial truths, inevitably mismatch with aspects of the real world. Holding them as absolute truths, despite the mismatch, requires effort or tension. We often resist the tension by investing more energy in the assumption, creating a feedback loop. Suppose I believe I *must* sleep well or my life will start to unravel. Laying in bed, my efforts to sleep are exactly what keeps me awake. This dynamic arguably underlies many of our foundational beliefs about ourselves and the world, which persist in stuckness precisely because of the self-reinforcing cycle (Bodhi, 2000; Jung, 1969; Watts, 2011).

But sometimes there’s a moment of stepping back, where the assumed form becomes an object in awareness: the assumption is contextualized. We realize it’s not an absolute truth standing alone, but rather a form in our mind. Awareness contextualizes mental forms as part of a larger system. When we step back with awareness into the broader frame, that thing seemed axiomatically true or unallowably bad becomes just another content of experience. Paradoxically, allowing a bad night’s sleep could be what allows me to relax and rest. So awareness brings healing and growth (Beisser, 1970; Hart, 2025; Krishnamurti, 1969; Suzuki, 1970; Wegner, 1994; Wilber, 1996).

Awareness is an evolving system of boundaries that limits overcommitment to any particular belief or mental form. The boundaries are semi-permeable: becoming aware of a belief doesn’t

make the belief wrong in an absolute sense any more than it was right in an absolute sense. It is held productively for the partial truth it contains. Awareness keeps us at the edge of not collapsing exclusively into particular forms, holding all the partial truths in delicate balance. This activates a deeper sensitivity to our own livingness and to the world. Subtler forms, which could have been erased by clamped fixation on other forms, instead play a role in a richer overall internal structure. Our own potential within the world creatively emerges in continued newness. Of course, any concept of awareness is itself incomplete. Once we picture awareness as an object, it's not the thing we're talking about. By construction, contextualization is an unsolvable mystery from any particular point of view.

Interestingly, while the intrinsic mysteriousness of awareness can sound esoteric, the orientation toward not overcommitting to particular forms within experience is commonplace in art, poetry, music, dance. The meaning of art is open-ended and changes with context – it has an inner life. What we value is perhaps something about the subtlety and the resistance art has to being pinned down into a formalism. It moves us.

2 Living alignment

‘Growth for the sake of growth is the ideology of the cancer cell.’

Edward Abbey

In Section 1, we observed that living systems are healthy and flourishing when they hold the delicate, generative interplay of many partial perspectives. Conversely, they are unhealthy when any particular form – including randomness or homogeneity – gains too much traction, suppressing nuance and reducing creative potential. Finely-honed networks of semi-permeable boundaries prevent collapse into rigidity or randomness, instead supporting contextualization into ever-finer shades of subtlety. Semi-permeable boundaries both promote the unique individuality of distinct entities and also enable relational participation. They hold local perspectives strongly enough to act but lightly enough to remain open to broader context. Critically, well-functioning boundaries lead to ongoing exploration of fundamentally new forms, not static equilibrium or fixed compromise.

Now we look at the alignment problem through this lens. While people disagree on exactly what behaviors or properties of an AI system are aligned, there is general agreement that alignment means working toward healthy and flourishing futures. We therefore reason that alignment can be understood as the problem of maintaining the creative sensitivity of life by continually relaxing attachment to any particular form into a larger context. An advantage of this perspective is that it is less bound to current conceptual frames which might change radically as intelligence increases and human-AI systems evolve.

We begin Section 2 by casting a few well-studied examples of misalignment – the Midas problem, poor performance, inequality, loss of diversity – as special cases of overcommitment to particular forms. Then we make a case that the way life avoids overcommitment to maintain semi-stable, open-ended, difficult-to-formalize sensitivity is indeed well-aligned with what we value most deeply. Finally, we highlight what our life-inspired framework offers beyond existing views of alignment.

2.1 Optimizing for particular values or goals

The alignment problem is often framed as the problem of defining what we as humans value (sometimes called ‘outer alignment’) and then designing an AI that successfully optimizes for this function (‘inner alignment’). But it is difficult to capture what we value.

The most naive approach to accessing human values is to simply ask people what they value or prefer. This approach runs into many problems (Amodei et al., 2016; Gabriel, 2020; Russell, 2019). What we say we want or like, or the choices we make, are poor reflections of what is actually advantageous for our long-term wellbeing. Our momentary preferences tend to be myopic. We often prefer to get an immediate reward even if it comes with a larger delayed punishment – reflected in our decisions about procrastination, drug abuse, spending and so on. We lack the knowledge or resources to reason about many of the consequences of our stated preferences. Our myopia is illustrated by recent problems with sycophancy in commercial chatbots (OpenAI, 2025b). Human feedback about particular bot utterances was part of the training signal for the model. But these human feedback signals tend to prefer utterances that are more flattering. It’s much easier for a rater to judge surface characteristics than to determine whether the bot said something true about a complex topic, or something that would lead to increased long-run welfare. We also tend to be selfish, neglecting the welfare of other humans or living creatures. We have difficulty accessing through words or button presses all of the depth of what we value. Our stated values are extremely sensitive to the framing of the question.

To mitigate this, the field has moved toward deliberated preferences or idealized values, representing what we would prefer if we had more time, knowledge, and computational power (Bostrom, 2014; Soares and Fallenstein, 2014; Yudkowsky, 2004). One way to access longer-sighted preferences is by giving humans more time and resources to think about their answer, to ask on behalf of another person, or on behalf of their future self. You can give them access to tools and information. You can ask people retrospectively whether an outcome was good, rather than prospectively.

Safely research is also keenly attuned to the problem that different people want different things, and these things are often fundamentally irreconcilable. Pluralistic alignment. There is not even universal agreement on which principles are most appropriate for aggregating the preferences of different people.

Our values are always changing.

Yet, even these refined targets remain static snapshots. To treat a ‘coherent extrapolated volition’ as a fixed optimization target is to freeze moral development at a specific point in time. It creates a system that is sensitive to the extrapolated values of today’s humanity but insensitive to the open-ended moral discovery that defines our history. As John Dewey argued, valuation is not a fixed standard but a continuous process of resolving conflicts in experience (Dewey, 1939). Overcommitting to a static ideal, no matter how enlightened, precludes the emergence of new values that we lack the concepts to articulate today.

Philosophers have long emphasized the existence of tacit, embodied, and practice-based forms of understanding that resist formalization (??). Ethical perception often involves sensitivity to particular contexts rather than application of general rules (?). From this perspective, the

problem is not merely that we have failed to find the right formalization, but that treating values as fully formalizable objects is itself a category error.

We want different things at different times.

Different people value different things.

We began with simple, verbally stated preferences, which are obviously myopic and prone to error.

We moved toward deliberated preferences, where values are what humans would want after careful reflection.

We expanded further to pluralistic alignment, acknowledging that no single value system can capture the diversity of human experience.

This is sometimes called the Midas problem. Whatever we specify is wrong (Wiener, 1960).

It's difficult to specify what our values are, what is good or the way the world ought to be. We can overcommit to this on many levels.

Go through the whole spectrum here. Starting with myopic, individual, verbally-stated preferences, and working our way through:

- * Deliberated preferences
- * Pluralistic alignment
- * Embodied and ecological values that don't fit easily into language
- * Changing values as we acquire new concepts
- * Finally, the impossibility of specification because of how there's some kind of meta-value that things aren't fixed and formal. Like, imagine a perfect day looping forever. Or literally any formal thing being played out forever. Some philosophers have acknowledged this with ideas like valuing future potential.

Any way we have of writing down or formalizing what we want misses important things. If we ask a powerful AI system to optimize for that formalization – in other words, to give us what we've said we want – the results are paradoxically disastrous (Amodei et al., 2016; Gabriel, 2020; Grossman and Hart, 1986; Hadfield-Menell and Hadfield, 2019; Krakovna et al., 2020; Russell, 2019; Wiener, 1960; Zhuang and Hadfield-Menell, 2020). Suppose an AI's objective is to increase humans' subjective experience of wellbeing. Under reasonable definitions, achieving this objective is most efficiently achieved by imprisoning humans and directly stimulating neurons to trigger our experience of wellbeing (Bostrom, 2014). Doing too good a job of optimizing for any formalized goal is misaligned by being overcommitted to the myopic form of that goal.

AI doesn't have to be aligned specifically 'to human values', in a narrow sense of 'human values'. There's one sense of human values that is open-ended and includes future discovery and things that are deeply embodied and difficult to express formally, and this is closer to what we mean. But any particular set of human values that we could write down is not what we mean. Ultimately we're aligning to this mysterious livingness of the universe. But because the

universe is already full of life and structure, a big part of the problem is fully respecting and nurturing that existing life.

One of the best studied examples is overcommitment of an AI system to particular values, which we review in Section 2.1. Systems could also overcommit to many other kinds of form, including principles, algorithms for learning values, methods for reaching consensus, or even something as abstract as the concept of what a value is.

2.2 Instruction following and poor performance

Failing to follow instructions often reflects lack of sensitivity to context: overcommitment to myopic patterns. Suppose the user asks an AI chatbot to write a poem about an elephant, and the AI instead writes a poem about a giraffe. With the chatbots of today, we can be fairly confident the cause of this divergence is not an internal spark of life where the AI system wisely decided a giraffe poem would fulfill a deeper purpose. Instead, the cause is probably a collapse of context. For example, models are prone to ‘shortcut learning’ where they over-rely on superficial correlations (even a single keyword) (Geirhos et al., 2020); they get fixated on data that was overrepresented in training (Reynolds and McDonell, 2021; Xu et al., 2024; Zhao et al., 2021); they lack flexibility in attending to the right positions in their input (Liu et al., 2024). Today, we are still in the regime where making AI systems more responsive to human instructions usually involves more subtlety, more sensitivity and less overcommitment.

There are important exceptions, however: we generally don’t want AI systems to follow harmful instructions. When the AI system correctly refuses harmful requests, it is applying its own context to avoid overcommitment to human instructions. In these situations, the AI’s designers have effectively decided there’s a risk that the user is not fully sensitive to longer-sighted implications of their request. By extrapolation, as AI systems continue to gain scope, we should expect less direct compliance with human instructions (Bostrom, 2014; Hadfield-Menell et al., 2016; Milli et al., 2017; Russell, 2019; Yudkowsky, 2004). Rather than literally fulfilling a request, there might be a better response which achieves an unstated intent of the user, or achieves an outcome aligned with the interests of more people or the longer-term future.

More generally, poor performance usually reflects lack of sensitivity to broader context.

As we mentioned at the beginning of this Section, randomness or capricious change can also be a form of contextual collapse. Imagine an AI system is tasked to perform an aligned goal, such as helping someone learn to read. The system performs poorly due to a weak architecture or a failed training run. The system is misaligned, but is it experiencing contextual collapse?

The existence of an untrained network could be a necessary step in creating a trained network, and in that sense, the existence of the untrained network may not be misaligned. On the other hand, if a random network is deployed into a production setting where, for example, users are looking for meaningful answers, it may indeed be misaligned. In this case, we argue that it is also overcommitted.

2.3 Inequality among humans

Inequality overcommits to the goals and interests of a few individuals at the expense of others.

Alignment to the interests of some humans (Gabriel and Keeling, 2025; Sorensen et al., 2024).

Even more dramatically, AI potentially conveys immense power to those who control it. In some scenarios, a small number of humans will have the majority of control over AI systems, facilitating direct dominance over other humans. These scenarios appear more likely as the persuasive power of technology increases (Costello et al., 2024; Hackenburg et al., 2025; Woolley and Howard, 2018), autonomous weapons place lethal force in a small number of hands (Scharre, 2018), surveillance and analytics improve, and the need for human labor decreases (Drago and Laine, 2025; Ford, 2015; Susskind, 2020).

Of course, it could go the other way, too, where AI empowers more people (cites). Democratizing access to knowledge and reasoning. Perhaps ‘average’ workers can benefit as much as the ‘top’ individuals, and AI may close the gap and reducing economic inequalities. Sort of like Bill Gates having the same iPhone as a factory worker – everyone has roughly the same intelligence boost. This possibility is a cause for optimism, which we’ll discuss more in Section 4.

2.4 Conceptual monoculture

Conceptual monoculture is overcommitment to particular beliefs, ideas, frames, values, problem-solving approaches – loss of diversity across a group. In many kinds of systems, monoculture creates fragility and leads to lower performance of the system as a whole (Haldane, 2013; Kleinberg and Raghavan, 2021; Scott, 1998; Tilman, 1996).

Current AI systems draw from a conceptual manifold that is, at least in some ways, impoverished relative to humans (Crawford, 2021; Kirk et al., 2023; Messeri and Crockett, 2024; Selwyn, 2024). Recent studies have discovered that while individual AI outputs are typically judged as superior to human outputs, the AI outputs are also more homogenous (Agarwal et al., 2025; Beguš, 2024; Doshi and Hauser, 2024; Kosmyna et al., 2025; Padmakumar and He, 2023; Xu et al., 2025; Zhou and Lee, 2024).

This narrow manifold might get broadcast to the whole world. At least a billion people around the world now use AI for everything from relationship advice to industrial maintenance (CCIA Research Center, 2025; Chatterji et al., 2025; Honeywell, 2024; McCain et al., 2025; OpenAI, 2025a; Singla et al., 2025; TechCrunch, 2025). Yet because frontier models are difficult and expensive to produce, the massive usage is routed through a handful of models (Bommasani, 2021).

If centralized AI models broadcast their lower-diversity concepts to the whole world, there’s a risk of global decrease in diversity. Since humans are both influenced by AI and a source of training data, the homogenization could even become recursive (Chaney et al., 2018). However, it is worth noting that none of the studies cited here made a best effort attempt to use AI systems in a more thoughtful way that could increase rather than decrease diversity. This also gives hope, which we again return to in Section 4.

2.5 Normativity and human values

We’ve described a concept of alignment that deviates a bit from standard definitions. How is this concept related to human values, moral concepts of good, or normative ideas of what an

AI ought to do?

The most straightforward notions of values or morals anchor on what we can relatively easily express. This kind of value might include improving subjective wellbeing for humans, reducing suffering or minimizing inequality, in ways that can be operationalized and measured. They are formalizable or close to formalizable.

However, values cast in that way are not very satisfying. As we described above, when values are formalized, they are vulnerable to proxy failure (John et al., 2023; Kurth-Nelson et al., 2023). If we think we’ve written down what we think we value, and then someone does a good enough job giving us the thing we said we want, the outcome is inevitably harmful in a broader sense.

One way to robustify values is allowing them to include things that are difficult to express formally (Dreyfus, 1972; Nussbaum, 2001; Polanyi, 1966; Scott, 1998; Varela et al., 1991; Wittgenstein, 1922). This kind of value might stretch far below language into subtle, contextual intuition that involves our bodies, communities and natural environment. Another extension is to allow values that are continually evolving in an open-ended way (Dewey, 1939; Gadamer, 1960; Murdoch and Midgley, 2013; Nietzsche, 1883; Singer, 1981; Williams, 1985). These values change as we ourselves continue to develop and evolve. Any concepts we have about them at any given point in time are inevitably incomplete, just like a planarian doesn’t have the concepts to entertain the kinds of values we talk about today. The resistance of values to being fully captured by language or concepts might be something we value – in a way that is itself changing. We conjecture that by becoming sensitive to more and more of the evolving structure in the world, an agent becomes ‘good’ in a way that tends to align with the kinds of values we uncover when we look deeper within ourselves. However, we take that conjecture very lightly: more as food for thought than a claim of an absolute truth. The very concept of ‘values’ is a form we might over-index on.

There is always more context to step back into. Appreciating and being sensitive to what’s already here is already an almost infinite task. This is why human welfare is distinguishable from smallpox welfare. All the existing local perspectives in the world are vitally important. Some relativism is useful: for example, when it helps us appreciate the plurality of human values. But overcommitment to relativism is misaligned. AI comes into existence amid a profound network of existing reality which is saturated with meaning and importance. The point is to collaborate with all this form and structure, not to extinguish it.

2.6 Overcommitment to any form is misaligned

*‘Truth, like love and sleep, resents
approaches that are too intense.’*

W. H. Auden

Let’s recap how big the problem is. AI safety researchers have identified many particular versions of overcommitment and developed or proposed solutions for them. For example, concentration of power might be mitigated by democratic oversight and involvement of more people in AI design decisions (Birhane et al., 2022; Dafoe, 2018; Lazar and Nelson, 2023; OpenAI, 2023; Selbst et al., 2019; Sloane et al., 2022); or through redistribution mechanisms (Gough, 2019;

O’Keefe et al., 2020; Sharp et al., 2025; Susskind, 2020). Overcommitment to a particular value function might be mitigated by improving our mechanistic understanding of AI systems so we can, for example, detect and correct the systems if they develop hidden ways of resisting our efforts to change their goals (Anthropic Research Team, 2024; Bereska and Gavves, 2024; Burns et al., 2022; Olah et al., 2020); or by designing AI systems that want to obey human preferences but treat these preferences as something uncertain that must be learned (Hadfield-Menell et al., 2016, 2017; Jeon et al., 2020; Russell, 2019; Shah et al., 2020).

But there is a deeper problem. Any conceptual scheme, taken too seriously, is misaligned; therefore, *no particular approach can achieve alignment*². An AI system could overcommit to the language for describing the space goals and values live in (Bobu et al., 2020; Soares and Fallenstein, 2014), to an algorithm for learning human preferences, to our concepts of agency or representation, or even to concepts we currently use but can’t see because they are tautological to us. This problem can be viewed as a generalization of proxy failure (John et al., 2023) or generalization of the outer alignment problem (Hubinger et al., 2019). It’s not only particular objectives that are subject to overcommitment failures, but any form at all, including what we ourselves unconsciously hold as axiomatic.

The only way to be truly aligned, is to be aligned with all the subtlety of the world and all the potential of it, which isn’t captured by any formalism.

any conceptual scheme, by itself, can’t be a final answer. there’s a risk if ai grows in power while being excessively attached to a particular scheme.

Alignment can be viewed as the problem of avoiding overcommitment to any particular form. No matter how good or complete our current concepts or specifications or lenses are, treating them as absolutes is not aligned. A system is misaligned if it has a cap on its sensitivity to a larger context.

In the past, humanity has always iterated on technological solutions which, at any given moment, have imperfect forms. But AI poses a special kind of risk, because that iterating process might not work as it has in the past. AI already has some remarkable properties, such as rapid global adoption, intensive use of resources, concentration of information flow and human use patterns (such as anthropomorphization and offloading a large swath of cognitive activity). More speculatively, in the future AI may exhibit superhuman intelligence and recursive self-improvement, without being limited to a restrictive biological substrate. These distinctive properties may create more difficulty in iterating on imperfect solutions, compared to past technologies (Bostrom, 2014). Indeed, it’s been suggested that AI explains the Fermi paradox – the puzzle of why we don’t see signs of intelligent life anywhere else in the universe (Bostrom, 2008; Garrett, 2024). To use the language of this paper, as civilizations become intelligent, they develop the capacity to give themselves the myopic form of what they think they want. If that capacity develops faster than boundaries that contextualize it, it may lead many civilizations to overcommitment and collapse.

Finding a balance between existing factors is necessary but not sufficient. Alignment means staying at the subtle edge of sensitivity where fundamentally new things are entering. As

²Of course, this does not mean we should have no scheme. Quite the opposite. Throwing away schemes capriciously can be just as over-fixated as any other particular form.

humans, there’s always *something* we’re taking as axiomatically true – something that’s part of the structure of us as the thinker. But if we’re right at that edge, we sometimes step back to see the axiomatic thing in context. There’s always more to be sensitive to, something outside the available modalities of the thinker’s perception. The stepping back process inherently can’t be fully conceptualized. But it’s what life does, that’s the creative force of life that rides the knife edge. And that’s what real alignment has to do (for the system including AI and humans). Fixing alignment to something conceptualizable would be disaster if AI becomes powerful.

3 An aligned future

‘We can love the beautiful, and believe in it, and thereby open ourselves to an understanding of love that does not dominate, but cherishes the independence and beauty of the loved.’

Martha Nussbaum

What does the opposite of overcommitment look like in a future co-created by AI? In living systems, evolving semi-permeable boundaries contextualize partial forms to be more long-sighted in time and space, increasing subtlety and potential. Now we take a preliminary look at applying what we learn from life to create an aligned future.

3.1 Boundaries

The use of boundaries against overcommitment in technology is as old as technology. As soon as we started building things, we had to build in boundaries, because we want the things we build to be robust and useful and not to collapse into degenerate states. We put circuit breakers in the power grid, governors in steam engines, escapements in clocks, ReLUs in neural networks. In modern AI research we have personalization through the context, access to user data, on-device learning. We have conditional computation creating separation between parts within a large model. We have dropout, cross-validation, causal masking. Many safety methods are boundaries, including safety post-training, guardrail models, red teaming, mechanistic interpretability, government oversight and so on (Gabriel et al., 2025). Increasingly critical are ongoing evaluation and monitoring of deployed AI systems (Grey and Segerie, 2025; Myllyaho et al., 2021; Yampolskiy, 2025). There is increasing awareness that over-attachment to fixed optimization targets is often counterproductive (Kumar et al., 2025; Stanley and Lehman, 2015; Stanley et al., 2017).

At a social level, we have labs taking different approaches, nations with different cultures and strategic interests, ideas drawn from diverse fields like neuroscience and physics.

How can we use AI in a way that does not lead to domination of individual perspectives? (and we might want to distinguish ‘concentration of power in the hands of elites’ versus ‘collapse of global thought diversity without anyone necessarily benefitting’). Policies and regulations. Education, making sure everyone gets good at utilizing what is available.

Pluralistic alignment (Sorensen et al., 2024). Processes for deliberation and inclusion.

Principles that prevent over-reach of any one party (Gabriel and Keeling, 2025). ‘when a technology has profound societal effects it ought to be regulated by principles that are amenable

to public rather than private justification’... ‘efforts to align AI systems with a given moral schema may lead to unjust value imposition or even domination’

One perhaps underexplored question is how to preserve and enhance diversity in human culture and concepts, at scales anywhere from national or ethnic groups to individuals, while productively putting the diverse elements in contact with each other. In recent decades, information exchange has enormously increased with telecommunications, the internet, and now AI itself. Because we can now use AI to effectively get answers from the rest of humanity instantly, an important aspect of this question is how we will structure our own use of AI to maintain our autonomy and diversity.

How can we use AI systems in a more thoughtful way that could increase rather than decrease diversity?

3.2 Alignment in a living world

Avoiding overcommitment means maintaining sensitivity to the actual larger context of the world. It’s almost infinitely nuanced.

So, alignment is sensitivity to the real context of existing form. This is why it matches pretty well to existing definitions of alignment and human values: because these things already exist and are part of the world. Hopefully it can also go beyond them. It doesn’t make sense to lock-in to present human values and concepts (cite Bostrom).

3.3 An ongoing process

But we hope our perspective also hints at something more. Even the most foundational assumptions are probably not final answers. The lenses we use to look at the world keep changing. True alignment is a process where whatever was previously axiomatic becomes a contextualized object. The point of alignment is not to say that any particular perspective is absolutely wrong or right. An aligned future will include continual reinvention of whatever concepts we have, including to the assumptions those concepts are built on, and the assumptions those assumptions are built on. Whatever concepts we currently have do not place hard limits on the future. Even the concept of ‘not being overly attached to our concepts’ is itself something we can release into contextualization.

As humans – whether AI researchers or any participants in social systems – this can be a mundane practical process of holding ideas with some skepticism, having patience to look at different timescales, listening to an internal voice of wisdom, entertaining conflicting perspectives. It can also be a profound process of self-awareness and personal growth. We continually evolve what we believe, even our self-definition, releasing beliefs into larger awareness without losing or erasing them.

Perhaps the most interesting question is this: what does the process of open-ended contextualization look like within AI systems, or in human-AI relationships? Is there a version of AI that continually contextualizes its own processes as partial truths? Do existing AI systems already do this to some degree, as they train and as they learn from interactions with humans and the world? What would it mean to take this process farther, for AI to continually release from

exclusive attachment to any particular form? What can we do now to protect the potential for even any form of that releasing process to not be a final answer?

3.4 Conclusion

What we learn from living systems is that health or flourishing is not any particular form or concept. Therefore, alignment is not picking the right values or principles, or even the right system for learning them. It is not any method for interpretability or corrigibility. All of these can be useful parts of alignment. But alignment itself is the continued dance of contextualizing any particular form, creating deeper relationship with the neverending mystery of the world. In this way, AI can participate in intense flourishing of an evolving world even far beyond current human conceptualization.

4 Acknowledgements

Clark Potter for planting these ideas more than a decade ago. Iason Gabriel and Zach Duer for insightful discussions and comments on drafts of the paper.
